

Potomac River

SAV Distribution and Status of Habitat

The well-defined linkage between water quality and submerged aquatic vegetation (SAV) distribution and abundance make SAV communities good barometers of the health of estuarine ecosystems. SAV is important not only as an indicator of water quality, but it is also a critical nursery habitat for many estuarine species. Blue crab post-larvae are 30 times more abundant in SAV beds than adjacent unvegetated areas. Similarly, several species of waterfowl are dependant on SAV as food when they over-winter in the Chesapeake region.

The Chesapeake Bay Program has developed new criteria for determining SAV habitat suitability of an area based on water quality. The “Percent Light at Leaf” habitat requirement assesses the amount of available light reaching the leaf surface of SAV after being attenuated in the water column and by epiphytic growth on the leaves themselves. The document describing this new model is found on the Chesapeake Bay Program website (www.chesapeakebay.net/pubs/sav/index.html). The older “Habitat Requirements” of five water quality parameters are still used for diagnostic purposes. Re-establishment of SAV is measured against the “Tier 1 Goal”, an effort to restore SAV to any areas known to contain SAV from 1971 to 1990.

The tidal fresh Potomac River has had highly variable SAV coverage, according to the Virginia Institute of Marine Science annual aerial survey (www.vims.edu/bio/sav/), peaking in 1991 at 4,632 acres, or 72% of the 6,405 acre Tier I goal (**figure 1**). From this high, SAV abundance decreased to a low of 1,369 acres in 1997 and rebounded in 1998, 1999 and 2000 to reach 3,879 or 61% of the Tier I goal. In 2001, the reported figure (1,969 acres) is down 50% from the 2000 number, however, it is important to remember that flight restrictions imposed after September 11, 2001 prevent VIMS from getting complete coverage. The SAV Beds fringe many of the shorelines. Ground-truthing by citizens, U. S. Geological Survey, U. S. Fish and Wildlife Service and Virginia Institute of Marine Science has found 11 species of SAV in this region, with wild celery, hydrilla and milfoil being the most reported ones. Data obtained from water quality monitoring stations located near Sheridan Point indicate that suspended solid levels pass, algae and phosphorous levels are borderline and light attenuation and percent light at leaf fail the SAV habitat requirements (**figure 2**). Nitrogen concentration is not applicable in tidal fresh regions.

Piscataway Creek has had increases in SAV coverage since 1995, though 1999 showed a large decrease from the 1998 levels (www.vims.edu/bio/sav/). The Tier I goal for this segment is 835 acres and the 1999 and 2000 SAV coverages were 15% and 38% of this number, respectively (**figure 1**), with the 2000 coverage being the most ever reported by the VIMS survey. In 2001, no data were obtained, again due to flight restrictions resulting from the terrorist attacks of 2001. Most of the 2000 SAV beds fringe the southern shore and the headwaters of this creek. Ground-truthing by citizens and staff from the U. S. Geological Survey has found 7 species in Piscataway Creek, listed in order of frequency recorded; hydrilla, naiads (2 species), coontail, wild celery, water stargrass, and milfoil. Water quality data from the station located near Calvert Manor indicate that algae levels and suspended solids pass in respect to the SAV

habitat requirements (**figure 2**). Light attenuation, percent light at leaf and phosphorous levels fail these requirements. Nitrogen concentration is not applicable in tidal fresh regions.

Mattawoman Creek has had steady increases in SAV coverage since 1995 (**figure 1**), surpassing the Tier I goal (134 acres) in 1998 (163 acres), 1999 (210 acres) and 2000 (331 acres or 247% of the goal) (www.vims.edu/bio/sav/). No data were obtained for 2001, again due to flight restrictions. Most of the previously identified beds fringe the shoreline, upstream of Swedes and Deep Points. Extensive ground-truthing by staff from the U. S. Geological Survey, U. S. Fish and Wildlife Service and citizens from Friends of Mattawoman Creek has found hydrilla, naiads, wild celery, coontail and milfoil (in order of frequency reported) in this creek. Water quality monitoring data from the station located near Swedes Point indicate that phosphorous and suspended solids levels meet and algae levels are borderline to the SAV habitat requirements (**figure 2**). Light attenuation and percent light at leaf fail the requirements. Nitrogen concentration is not applicable in this tidal fresh creek.

In the oligohaline (low salinity) Potomac River, between Quantico and Mathias Points, has seen fairly consistent SAV coverage since 1984, ranging from a low of 2,529 acres in 1995 to a high of 4,306 acres in 1998 (**figure 1**), at which time the coverage exceeded the Tier I goal of 4,264 acres (www.vims.edu/bio/sav/). The 2001 coverage was 3,071 acres or 72% of the Tier I goal, though again these are partial data. The largest SAV beds in the Maryland portion of the river are found in Chicamuxen Creek and then fringing the shoreline to Smith Point, then fringing the shoreline from Maryland Point to just upstream of Pope Creek, including the shorelines of Nanjemoy Creek and Port Tobacco River. On the Virginia side, there are fringing beds from Shipping to Clifton Points, near the mouth of Potomac Creek, near Somerset Beach, the mouth of Chotank Creek, and fringing the shoreline around Mathias Point. Ground-truthing by citizens and staff from U. S. Geological Survey, U. S. Fish and Wildlife Service and Virginia Institute of Marine Science has found 13 different species of SAV, with the three most often reported being milfoil, wild celery, hydrilla. Water quality data from the monitoring stations near Moss and Maryland Points indicate that only algae levels meet the SAV habitat requirements, percent light at leaf and concentration of suspended solids are borderline and light attenuation and phosphorus levels fail (**figure 2**). Nitrogen concentration is not applicable in this area.

In the mesohaline (moderate salinity) Potomac River, downstream of Mathias point to Point Lookout has had steady increases in SAV coverage since 1992 (when there was 238 acres), passing the Tier I goal of 989 acres and reaching the highest recorded level in 1999 of 2,351 acres (or 238% of the Tier I goal) (www.vims.edu/bio/sav/) However, the 2000 coverage was down 55% to 1,045 acres due to heavy springtime algal booms, but even this value exceeds the Tier I goal (**figure 1**). In 2001, SAV coverage rebounded to 1,739 acres or 176% of the Tier I goal. On the Maryland side, there are fringing beds from the Route 301 bridge to Cobb Island, scattered throughout the Wicomico River and St. Clements Bay. There are a few small beds downstream from here, but no large beds until St. George Island with fringing beds through much of the lower St. Mary's River. On the Virginia side, there is a large fringing bed from Mathias Point to the Upper Machodoc Creek. Ground-truthing by citizens and staff from

Patuxent River Park, Patuxent Naval Air Station, U. S. Geological Survey, U. S. Fish and Wildlife Service and Virginia Institute of Marine Science has identified 11 species with milfoil, horned pondweed and wild celery the three most frequently reported ones. Data from the three water quality monitoring stations (located at the Route 301 bridge, near Ragged Point and Point Lookout) indicates that water quality is fairly good in this area with light attenuation and nitrogen levels being borderline, while percent light at leaf, concentrations of suspended solids, algae and phosphorous pass the SAV habitat requirements (**figure 2**).
